Introduction

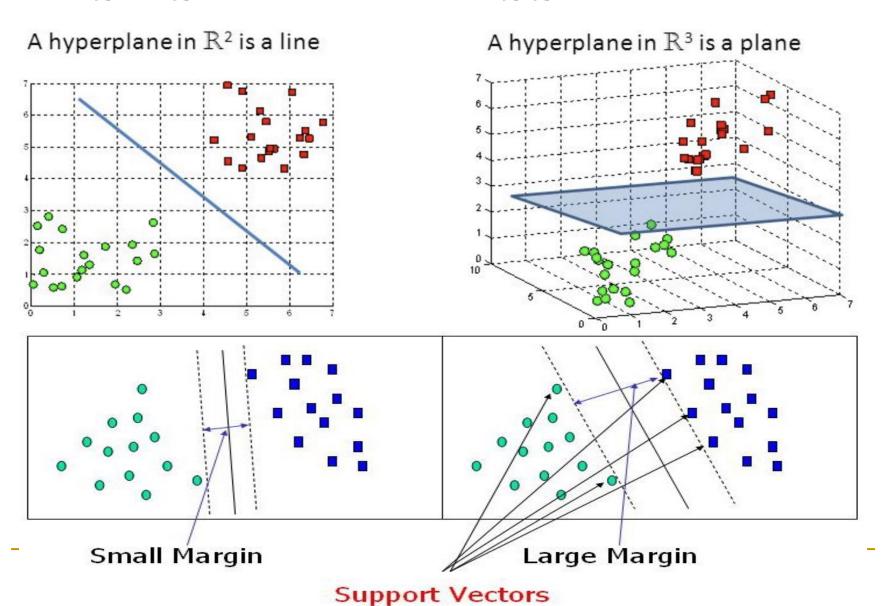

Supervised learning algorithm

- SVM algorithm was invented by Vladimir N.
 Vapnik and Alexey Ya. Chervonenkis in 1963.
- The objective of the support vector machine algorithm is to find a hyperplane in an Ndimensional space (N — the number of features) that distinctly classifies the data points.
- Support vector machine is highly preferred because of high accuracy with less computation.
- It can be used as regression and classification but it is widely used as classifier.

Objectives To find a hy space(N — distinctly classes.

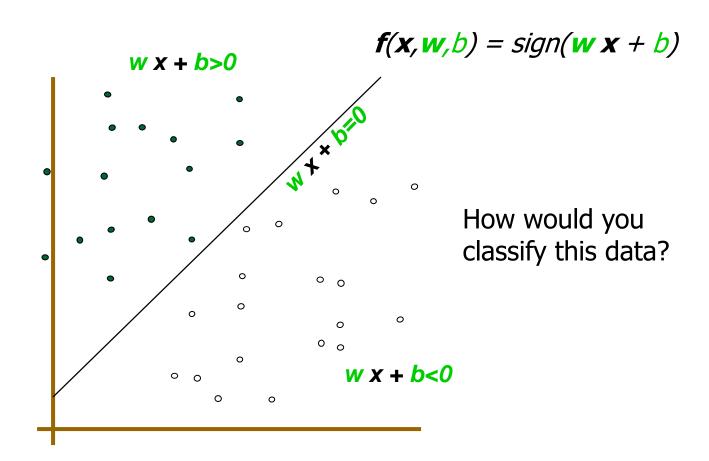

- To find a plane that has the maximum margin, i.e the maximum distance between data points of both classes.
- Maximizing the margin distance provides some reinforcement so that future data points can be classified with more confidence.

Hyperplanes and Support Vectors

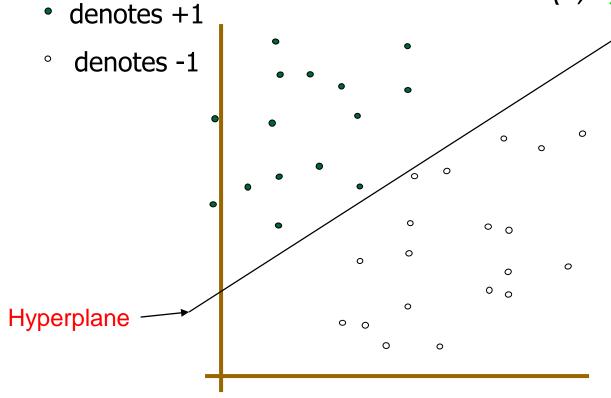

Linear Classifiers $f \longrightarrow V$ est

- denotes +1
- denotes -1

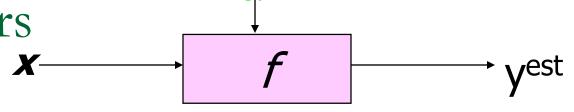

Linear Classifiers **Y** **Y

$$f(x, w, b) = sign(w x + b)$$

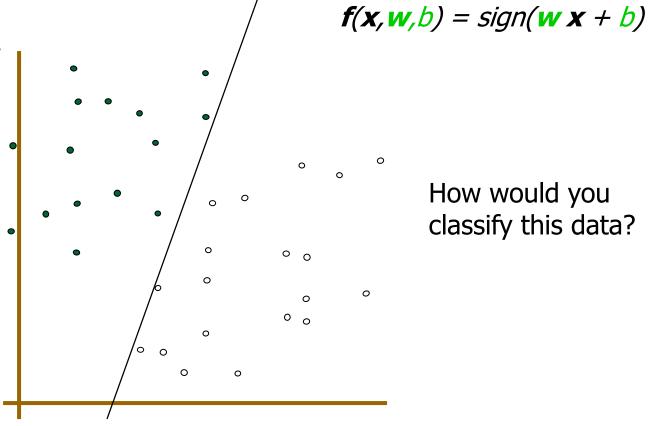

How would you classify this data?

Linear Classifiers

- denotes +1
- denotes -1

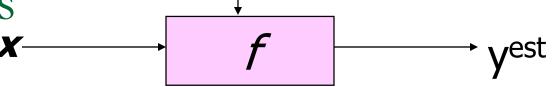

How would you classify this data?

Linear Classifiers f(x, w, b) = sign(w x + b)denotes +1 denotes -1 Any of these would be fine..

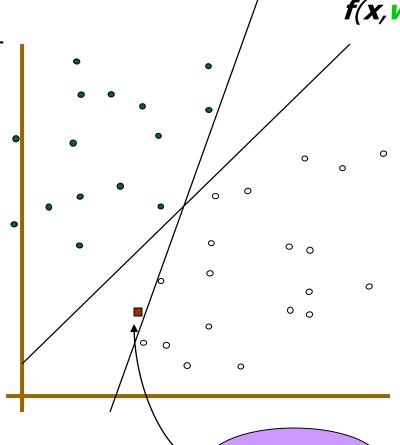

0 0

..but which is best?

Linear Classifiers

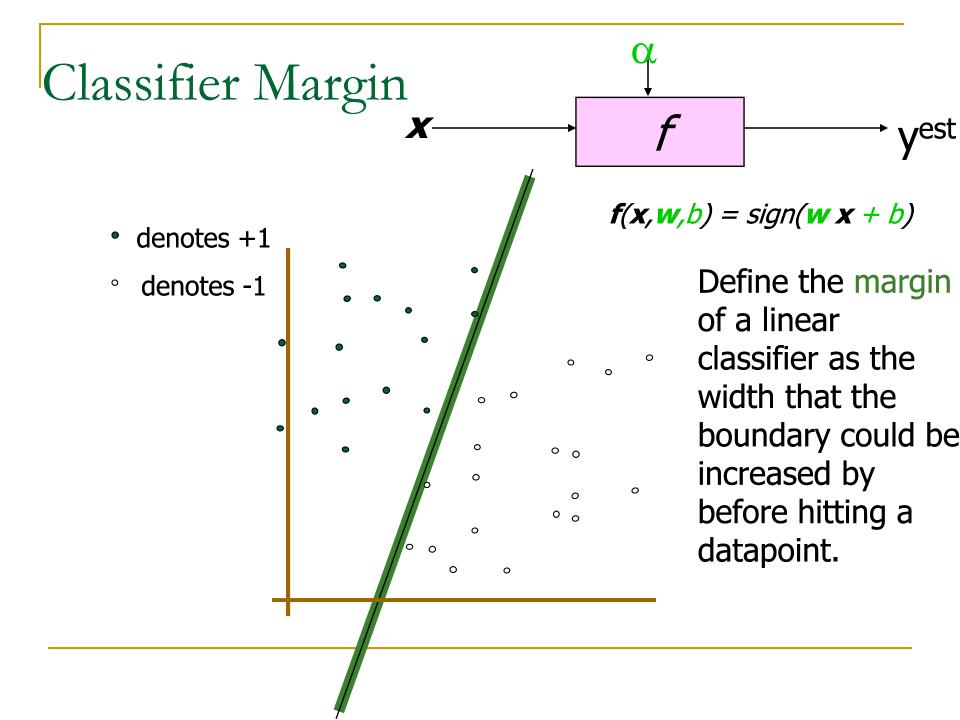

- denotes +1
- ° denotes -1

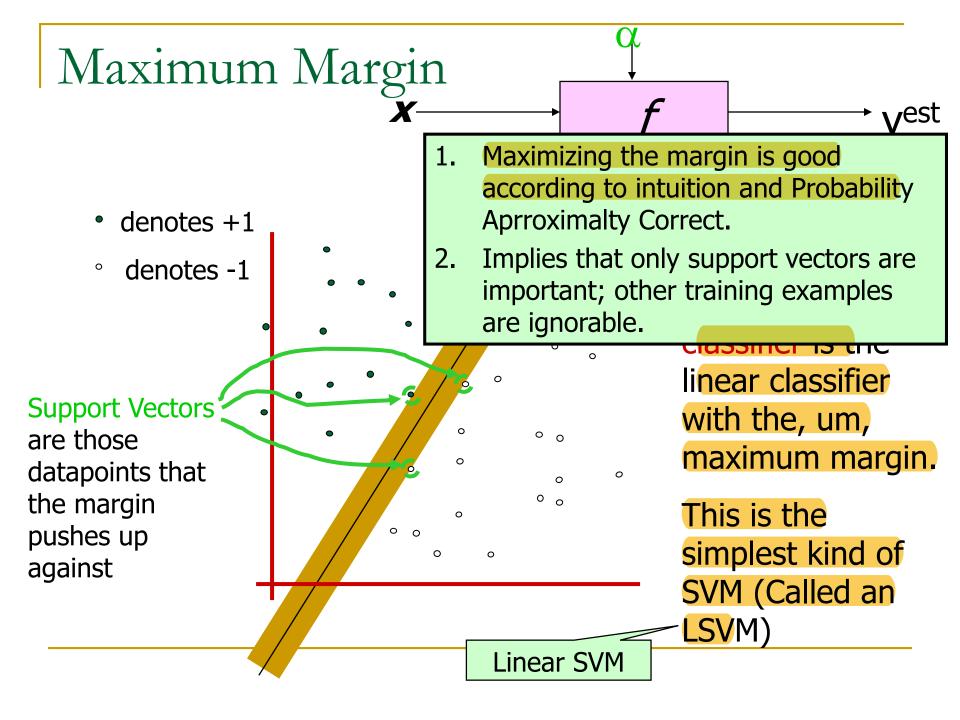

f(x, w, b) = sign(w x + b)

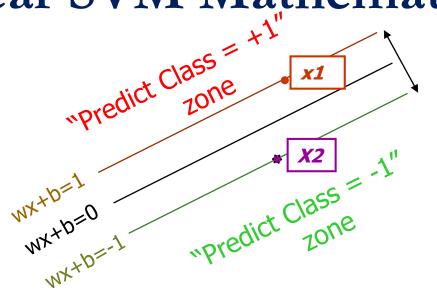

How would you classify this data?

Misclassified to +1 class

Linear SVM Mathematically

M=Margin Width

$$\Rightarrow \mathbf{w}^T \mathbf{x_2} + b = 1 \text{ where } \mathbf{x_2} = \mathbf{x_1} + \lambda \mathbf{w}$$

$$\Rightarrow \mathbf{w}^T(\mathbf{x_1} + \lambda \mathbf{w}) + b = 1$$

$$\Rightarrow \mathbf{w}^T \mathbf{x_1} + b + \lambda \mathbf{w}^T \mathbf{w} = 1 \text{ where } \mathbf{w}^T \mathbf{x_1} + b = -1$$

$$\Rightarrow -1 + \lambda \mathbf{w}^T \mathbf{w} = 1$$

$$\Rightarrow \lambda \mathbf{w}^T \mathbf{w} = 2$$

$$\Rightarrow \lambda = \frac{2}{\mathbf{w}^T \mathbf{w}} = \frac{2}{\|\mathbf{w}\|^2}$$

And so, the distance
$$\lambda \|\mathbf{w}\|$$
 is $\frac{2}{\|\mathbf{w}\|^2} \|\mathbf{w}\| = \frac{2}{\|\mathbf{w}\|} = \frac{2}{\sqrt{\mathbf{w}^T \mathbf{w}}}$

$$\lambda = \frac{2}{w^T w} = \frac{2}{\|w\|^2}$$

Distance=
$$\lambda ||w|| = \frac{2}{||w||^2} ||w|| = \frac{2}{||w||} = \frac{2}{\sqrt{w^T w}}$$

Linear SVM Mathematically

Goal: 1) Correctly classify all training data

$$|wx_i + b| \ge 1 \qquad \text{if } y_i = +1 \\ |wx_i + b| \le 1 \qquad \text{if } y_i = -1 \\ |y_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\ |x_i(wx_i + b)| \ge 1 \qquad \text{for all } i \le 2 \\$$

We can formulate a Quadratic Optimization Problem and solve for w and b

• Minimize
$$\Phi(w) = \frac{1}{2}w^t w$$

subject to $y_i(wx_i + b) \ge 1$ $\forall i$

Solving the Optimization Problem

```
Find w and b such that \Phi(\mathbf{w}) = \frac{1}{2} \mathbf{w}^{\mathrm{T}} \mathbf{w} is minimized; and for all \{(\mathbf{X_i}, y_i)\}: y_i (\mathbf{w}^{\mathrm{T}} \mathbf{x_i} + b) \ge 1
```

- Need to optimize a quadratic function subject to linear constraints.
- Quadratic optimization problems are a well-known class of mathematical programming problems, and many (rather intricate) algorithms exist for solving them.
- The solution involves constructing a dual problem where a Lagrange multiplier α_i is associated with every constraint in the primary problem:

```
Find \alpha_1...\alpha_N such that \mathbf{Q}(\mathbf{\alpha}) = \sum \alpha_i - \frac{1}{2} \sum \alpha_i \alpha_j y_i y_j \mathbf{x_i}^T \mathbf{x_j} \text{ is maximized and}
(1) \sum \alpha_i y_i = 0
(2) \alpha_i \geq 0 \text{ for all } \alpha_i
```

The Optimization Problem Solution

The solution has the form:

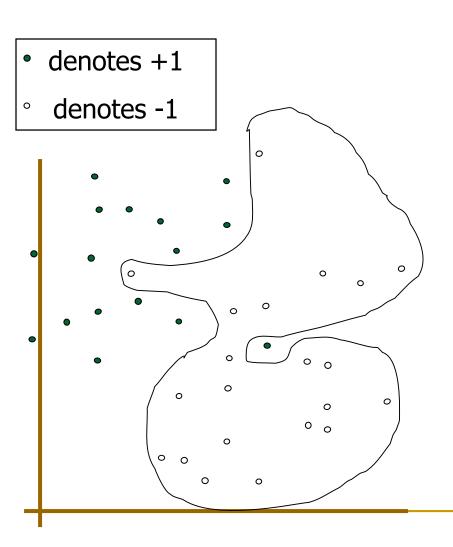

$$\mathbf{w} = \sum \alpha_i y_i \mathbf{x_i}$$
 $b = y_k - \mathbf{w^T x_k}$ for any $\mathbf{x_k}$ such that $\alpha_k \neq 0$

- Each non-zero $α_i$ indicates that corresponding $\mathbf{x_i}$ is a support vector.
- Then the classifying function will have the form:

$$f(\mathbf{x}) = \sum \alpha_i y_i \mathbf{x_i}^{\mathsf{T}} \mathbf{x} + b$$

- Notice that it relies on an inner product between the test point x and the support vectors x_i – we will return to this later.
- Also keep in mind that solving the optimization problem involved computing the inner products x_i^Tx_j between all pairs of training points.

Dataset with noise

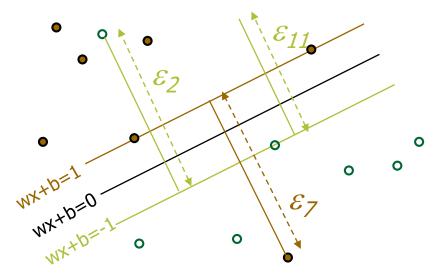

- Hard Margin: So far we require all data points be classified correctly
 - No training error
- What if the training set is noisy?
 - Solution 1: use very powerful kernels

OVERFITTING!

Soft Margin Classification

Slack variables ξi can be added to allow misclassification of difficult or noisy examples.

What should our quadratic optimization criterion be?

Minimize

$$\frac{1}{2}\mathbf{w}\mathbf{w} + C\sum_{k=1}^{R} \varepsilon_{k}$$

Hard Margin v.s. Soft Margin

The old formulation:

```
Find w and b such that \mathbf{\Phi}(\mathbf{w}) = \frac{1}{2} \mathbf{w}^{\mathrm{T}} \mathbf{w} \text{ is minimized and for all } \{(\mathbf{x_i}, y_i)\}y_i (\mathbf{w}^{\mathrm{T}} \mathbf{x_i} + \mathbf{b}) \ge 1
```

The new formulation incorporating slack variables:

```
Find w and b such that  \Phi(\mathbf{w}) = \frac{1}{2} \mathbf{w}^{\mathrm{T}} \mathbf{w} + C \sum_{i} \xi_{i}  is minimized and for all \{(\mathbf{x_i}, y_i)\}  y_i (\mathbf{w}^{\mathrm{T}} \mathbf{x_i} + b) \ge 1 - \xi_i  and \xi_i \ge 0 for all i
```

Parameter C can be viewed as a way to control overfitting.

Linear SVMs: Overview

- The classifier is a separating hyperplane.
- Most "important" training points are support vectors; they define the hyperplane.
- Quadratic optimization algorithms can identify which training points x_i are support vectors with non-zero Lagrangian multipliers α_i.
- Both in the dual formulation of the problem and in the solution training points appear only inside dot products:

```
Find \alpha_1...\alpha_N such that \mathbf{Q}(\alpha) = \sum \alpha_i - \frac{1}{2} \sum \alpha_i \alpha_j y_i y_j \mathbf{x_i}^T \mathbf{x_j} \text{ is maximized and}
(1) \sum \alpha_i y_i = \mathbf{0}
```

(2) $0 \le \alpha_i \le C$ for all α_i

$$f(\mathbf{x}) = \sum \alpha_i y_i \mathbf{x_i}^{\mathsf{T}} \mathbf{x} + \mathbf{b}$$

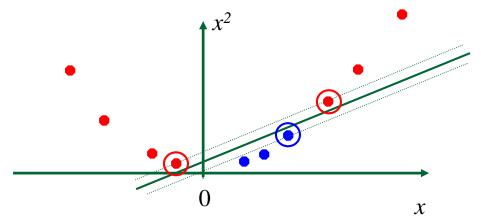

Non-linear SVMs

Datasets that are linearly separable with some noise work out great:

But what are we going to do if the dataset is just too hard?

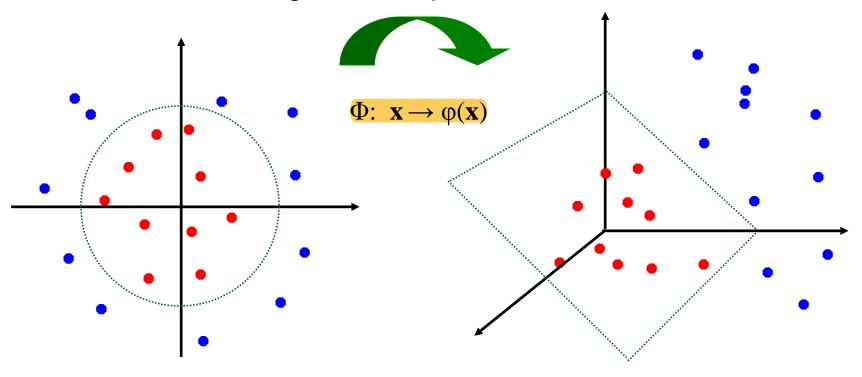

How about... mapping data to a higher-dimensional space:

Non-linear SVMs: Feature spaces

General idea: the original input space can always be mapped to some higher-dimensional feature space where the training set is separable:

The "Kernel Trick"

- The linear classifier relies on dot product between vectors $K(x_i,x_j)=x_i^Tx_j$
- If every data point is mapped into high-dimensional space via some transformation $\Phi: \mathbf{x} \to \phi(\mathbf{x})$, the dot product becomes:

$$K(\mathbf{x_i}, \mathbf{x_j}) = \varphi(\mathbf{x_i})^{\mathrm{T}} \varphi(\mathbf{x_j})$$

- A kernel function is some function that corresponds to an inner product in some expanded feature space.
- Example:

2-dimensional vectors $\mathbf{x}=[x_1 \ x_2]$; let $K(\mathbf{x_i},\mathbf{x_j})=(1+\mathbf{x_i}^T\mathbf{x_j})^2$, Need to show that $K(\mathbf{x_i},\mathbf{x_j})=\phi(\mathbf{x_i})^T\phi(\mathbf{x_j})$: $K(\mathbf{x_i},\mathbf{x_j})=(1+\mathbf{x_i}^T\mathbf{x_j})^2$,

What Functions are Kernels?

For some functions $K(\mathbf{x_i}, \mathbf{x_j})$ checking that $K(\mathbf{x_i}, \mathbf{x_i}) = \phi(\mathbf{x_i})^{\mathrm{T}} \phi(\mathbf{x_i})$ can be cumbersome.

Mercer's theorem:

Every semi-positive definite symmetric function is a kernel

Semi-positive definite symmetric functions correspond to a semi-positive definite symmetric Gram matrix:

	$K(\mathbf{x}_1,\mathbf{x}_1)$	$K(\mathbf{x_1},\mathbf{x_2})$	$K(\mathbf{x}_1,\mathbf{x}_3)$	• • •	$K(\mathbf{x}_1,\mathbf{x}_N)$
	$K(\mathbf{x}_2,\mathbf{x}_1)$	$K(\mathbf{x}_2,\mathbf{x}_2)$	$K(\mathbf{x}_2,\mathbf{x}_3)$		$K(\mathbf{x}_2,\mathbf{x}_N)$
	• • •	•••	• • •	• • •	
	$K(\mathbf{x}_{N},\mathbf{x}_{1})$	$K(\mathbf{x_N},\mathbf{x_2})$	$K(\mathbf{x_N},\mathbf{x_3})$		$K(\mathbf{x_N},\mathbf{x_N})$

Examples of Kernel Functions

- Linear: $K(\mathbf{x_i}, \mathbf{x_j}) = \mathbf{x_i}^T \mathbf{x_j}$
- Polynomial of power p: K(x_i,x_j)= (1+ x_i Tx_j)^p
- Gaussian (radial-basis function network):

$$K(\mathbf{x_i}, \mathbf{x_j}) = \exp(-\frac{\|\mathbf{x_i} - \mathbf{x_j}\|^2}{2\sigma^2})$$

Sigmoid: $K(\mathbf{x_i}, \mathbf{x_j}) = \tanh(\beta_0 \mathbf{x_i}^T \mathbf{x_j} + \beta_1)$

Non-linear SVMs Mathematically

Dual problem formulation:

Find $\alpha_1...\alpha_N$ such that $Q(\alpha) = \sum \alpha_i - \frac{1}{2} \sum \alpha_i \alpha_j y_i y_j K(\mathbf{x_i}, \mathbf{x_j}) \text{ is maximized and}$ (1) $\sum \alpha_i y_i = 0$ (2) $\alpha_i \geq 0$ for all α_i

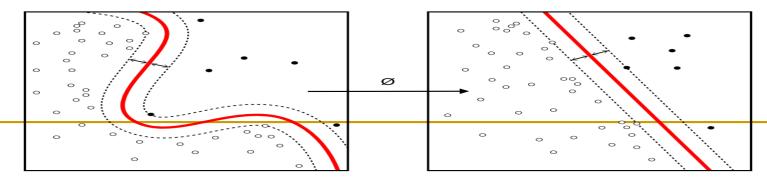

The solution is:

$$f(\mathbf{x}) = \sum \alpha_i y_i K(\mathbf{x}_i, \mathbf{x}_j) + b$$

• Optimization techniques for finding α_i 's remain the same!

Nonlinear SVM - Overview

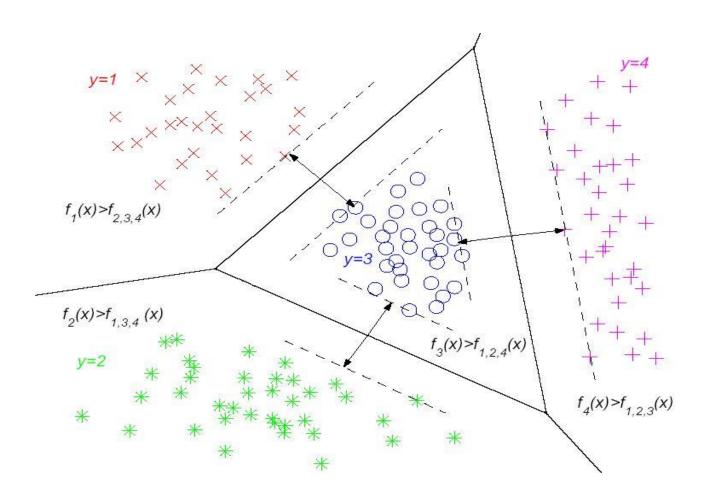

- SVM locates a separating hyperplane in the feature space and classify points in that space
- It does not need to represent the space explicitly, simply by defining a kernel function
- The kernel function plays the role of the dot product in the feature space.

Properties of SVM

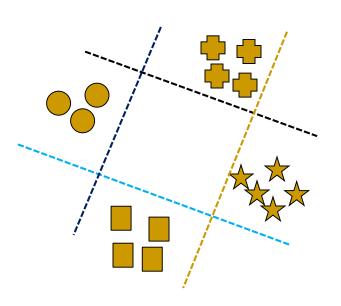

- Flexibility in choosing a similarity function
- Sparseness of solution when dealing with large data sets
 - only support vectors are used to specify the separating hyperplane
- Ability to handle large feature spaces
 - complexity does not depend on the dimensionality of the feature space
- Overfitting can be controlled by soft margin approach
- Nice math property
 - a simple convex optimization problem which is guaranteed to converge to a single global solution
- Feature Selection

Multi-class SVM

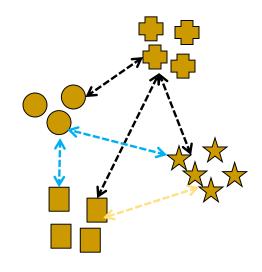

1 -against- All

- Or "one-against-rest", a tree algorithm
- Decomposed to a collection of binary classifications
- k decision functions, one for each class (w_k) T $\phi x + b_k$, $k \in Y$
- The kth classifier constructs a hyperplane between class n and the k-1 other classes
- Class of $x = \operatorname{argmax}_{i}\{(w_i)T \cdot \phi(x) + b_i\}$

1 -against- 1

- $\frac{k(k-1)}{2}$ classifiers where each one is trained on data from two classes
- For training data from ith and jth classes, run binary classification
- Voting strategy: If $sign((w_{ij})T.\varphi x + b_{ij})$ says x is in class i, then add 1 to class i else to j.
- Assign x to class with largest vote (Max wins)

$$\frac{4(4-1)}{2} = 6 SVM$$

Multi-class SVM Approaches

1-against-all

 Each of the SVMs separates a single class from all remaining classes (Cortes and Vapnik, 1995)

1-against-1

■ Pair-wise. k(k-1)/2, $k \in Y$ SVMs are trained. Each SVM separates a pair of classes (Fridman, 1996)

Performance similar in some experiments (Nakajima, 2000)

Time complexity similar: k evaluation in 1-all, k-1 in 1-1

Advantages of SVM

- Effective in high dimensional cases.
- Its memory efficient as it uses a subset of training points in the decision function called support vectors.
- Different kernel functions can be specified for the decision functions and its possible to specify custom kernels.
- Support vector machine works comparably well when there is an understandable margin of dissociation between classes.

Weakness of SVM

- It is sensitive to noise
 - A relatively small number of mislabeled examples can dramatically decrease the performance
 - SVM does not perform very well when the data set has more noise i.e. target classes are overlapping.
- In cases where the number of features for each data point exceeds the number of training data samples, the SVM will underperform.
- As the support vector classifier works by putting data points, above and below the classifying hyperplane there is no probabilistic explanation for the classification.
- Support vector machine algorithm is not acceptable for large data sets.

SVM Applications

- SVM has been used successfully in many real-world problems
 - text (and hypertext) categorization
 - image classification
 - bioinformatics (Protein classification, Cancer classification)
 - hand-written character recognition

Application 1: Cancer Classification

- High Dimensional
 - p>1000; n<100
- Imbalanced
 - less positive samples

$$K[x,x] = k(x,x) + \lambda \frac{n^+}{N}$$

	Many	irre	levant	features	3
--	------	------	--------	----------	---

Noisy

Genes							
Patients	g-1	g-2	•••••	g-p			
P-1							
p-2							
p-n							

FEATURE SELECTION

In the linear case, w_i² gives the ranking of dim i

SVM is sensitive to noisy (mis-labeled) data 🙈

Application 2: Text Categorization

- Task: The classification of natural text (or hypertext) documents into a fixed number of predefined categories based on their content.
 - email filtering, web searching, sorting documents by topic, etc..
- A document can be assigned to more than one category, so this can be viewed as a series of binary classification problems, one for each category

Representation of Text

IR's vector space model (aka bag-of-words representation)

- A doc is represented by a vector indexed by a pre-fixed set or dictionary of terms
- Values of an entry can be binary or weights

$$\phi_i(x) = \frac{\mathrm{tf}_i \log (\mathrm{idf}_i)}{\kappa},$$

- Normalization, stop words, word stems
- Doc $x => \phi(x)$

Text Categorization using SVM

- The distance between two documents is $\varphi(x) \cdot \varphi(z)$
- $K(x,z) = \langle \varphi(x) \cdot \varphi(z) \rangle$ is a valid kernel, SVM can be used with K(x,z) for discrimination.
- Why SVM?
 - -High dimensional input space
 - -Few irrelevant features (dense concept)
 - -Sparse document vectors (sparse instances)
 - -Text categorization problems are linearly separable

Some Issues

Choice of kernel

- Gaussian or polynomial kernel is default
- if ineffective, more elaborate kernels are needed.
- domain experts can give assistance in formulating appropriate similarity measures

Choice of kernel parameters

- e.g. σ in Gaussian kernel
- σ is the distance between closest points with different classifications.
- In the absence of reliable criteria, applications rely on the use of a validation set or cross-validation to set such parameters.
- Optimization criterion Hard margin v.s. Soft margin
 - a lengthy series of experiments in which various parameters are tested
- Requires full labeling of input data
- Parameters of a solved model are difficult to interpret.
- The SVM is only directly applicable for two-class tasks

Questions

Problem 1

- Consider a hyperplane defined by a line $y = x_1 2x_2$.
- Determine the correct prediction of following data points.
 - **(1, 0)**
 - **(1,1)**

Solutions

■ Draw the hyperplane $y = x_1 - 2x_2 = w^T x$.

Correctly
Classified the
data point (1,0),
since it is positive

Problem 2

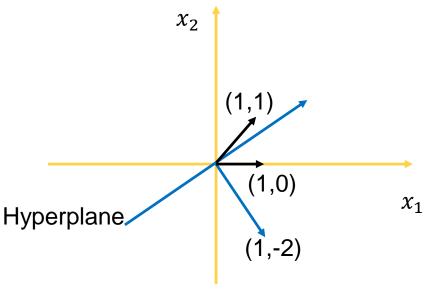

- Consider a hyperplane defined by a line $y = x_1 2x_2$.
- Determine the distance of the following points from the hyperplane.
 - **-** (-1, 2)
 - **(1,0)**
 - **(1,1)**

Solutions

- Distance of a point from hyperplane is calculated using following formula:

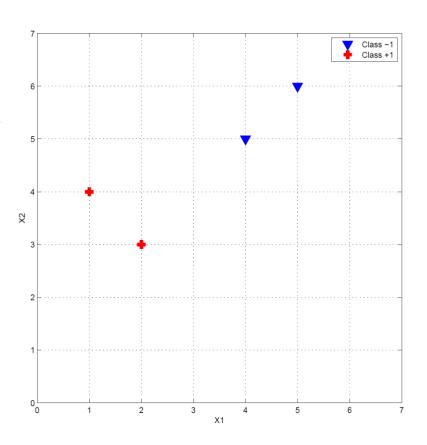

- **1** (1,0)
- **(1,1)**

Distance of point (-1,2) is $\frac{\times -1 - 2 \times 2}{\sqrt{(1)^2 + (-2)^2}} = -\frac{5}{\sqrt{5}} = -\sqrt{5}$

Problem 3

Support vector machines learn a decision boundary leading to the largest margin from both classes. You are training SVM on a tiny dataset with 4 points shown in Figure. This dataset consists of two examples with class label -1 9 (denoted with plus), and two examples with class label +1 (denoted with triangles). i. Find the weight vector w and bias b. What's the equation corresponding to the decision boundary?

Solution

- SVM tries to maximize the margin between two classes. Therefore, the optimal decision boundary is diagonal and it crosses the point (3,4).
- It is perpendicular to the line between support vectors (4,5) and (2,3), hence it is slope is m = -1.
- Thus the line equation is $x_2 4 = -1(x_1 3) = x_1 + x_2 = 7$. From this equation, we can deduce that the weight vector has to be of the form (w_1, w_2) , where $w_1 = w_2$. It also has to satisfy the following equations:
 - $ward 2w_1 + 3w_2 + b = 1$ and $4w_1 + 5w_2 + b = 1$
 - Hence, $w_1 = w_2 = -\frac{1}{2}$ and $b = \frac{7}{2}$

Solution...
